New Clinical Evidence through 5 Years

Positive results continue: 93% of subjects showed a decrease in refractive error change
New Clinical Evidence through 5 Years: VTI’s Extended Depth of Focus, Center Distance Lens Continues to be Effective in Real-World Practice

Results:
- Retrospective case series analysis - 153 subjects, 5 years, 13 real-world practices.
- 93% of subjects showed a decrease in refractive error change, with 65% showing a decrease of 70% or more.
- At all points in time, the average amount of myopia progression observed was ≤ 0.125D from baseline.
- The average refractive error change slowed by 0.90D (or 90%) as compared to baseline from 6-59 months.

Background:
A 2018 retrospective case series analysis of 32 myopic children, in a real-world evidence retrospective cohort analysis (mean age: 10.98±2.95 years) from 10 practice locations in the United States wearing daily disposable soft multifocal lenses (NaturalVue® Multifocal 1 Day, Visioneering Technologies, Inc., Alpharetta, GA) exhibited significant reductions in myopic progression. In the initial retrospective cohort analysis, the duration of wear for the 32 patients was just under 1 year (Mean 10.94±4.76 months; Range 6 to 25 months). The study authors subsequently endeavored to report on the NaturalVue Multifocal efficacy over an expanded wear time/follow up of about five years (59 months) and with a larger cohort of 153 patients who had not previously used other interventions for myopic progression such as soft multifocal contact lenses, orthokeratology, or atropine.

Recently, new 5-year data was presented with the VTI extended depth of focus, center distance, daily disposable multifocal contact lenses*. A summary of the results is outlined here:

Methodology:
A retrospective case series analysis of data from 153 patients (305 eyes) fit with the multifocal lens between December 2014 and December 2019 (59 months), from 13 practices in the United States was conducted. The patients showed at least -0.50D of myopic progression in at least one eye prior and had not previously used other interventions for myopic progression (soft multifocal contact lenses, orthokeratology, or atropine).
Results Detail:

- 93% of wearers showed a decrease in myopia progression.
  - Additionally, 65% of wearers showed a decrease in myopia progression of 70% or greater. [Figure 1]

- The average myopia progression slowed by approximately 0.90D or 90% compared to baseline, statistically significant at all points in time (P<0.05). [Figures 2 and 3]
  - The average myopia progression while wearing the lens never exceeded more than about 0.125D from baseline.

- Axial length change was measured for a subset of the population. The average change was approximately 0.10 mm per year through 35 months of follow up. [Figure 4]

If increase in RE Change: Avg = -0.29 ± 0.30 (-0.001 to -1.375)
95% CI: -0.09, -0.48

Figure 2: Amount of Refractive Error (D) as Compared to Baseline (BL) Mean, 95% CI (All P < 0.05 to BL)

- RE Change per Year at BL with Prior CX (n=335)
- RE Change from BL at 6-11M (n=123)
- RE Change from BL at 12-17M (n=150)
- RE Change from BL at 18-23M (n=150)
- RE Change from BL at 24-29M (n=150)
- RE Change from BL at 30-35M (n=150)
- RE Change from BL at 36-41M (n=150)
- RE Change from BL at 42-47M (n=150)
- RE Change from BL at 48-53M (n=150)
- RE Change from BL at 54-59M (n=18)

- 0.85D (88%) Reduction in RE change as compared to BL AFTER 1 YEAR
- 0.85D (88%) Reduction in RE change as compared to BL AFTER 2 YEARS
- 0.93D (90%) Reduction in RE change as compared to BL AFTER 3 YEARS
- 0.97D (101%) Reduction in RE change as compared to BL AFTER 4 YEARS

From 6 through 59 M, Average RE change never exceeded 0.125D from baseline

Month (M) • Refractive Error (RE) • Change (D) • As Compared to Baseline (BL)
Figure 3
Amount of Refractive Error (D) as Compared to Baseline (BL) Mean, 95% CI (All P < 0.05 to BL) Paired Data

A paired analysis for the refractive error progression observed for years 1 through 5 (59m)

Figure 4
Amount of Axial Length (mm) Change as Compared to Baseline (BL) Mean, 95% CI (All P < 0.05 to BL)

From 6 through 59 months, Average AL change was 0.10mm/year or less. “Normal” emmetropic growth in this age range: 0.10-0.13mm/yr.
Conclusions of the study
The VTI lens continues to be proven effective in reducing myopic progression, even after 5 years for some children. Further research is needed to understand the clinical importance of the observed differences as well as long-term outcomes.

Limitations of the analysis:
• The analysis included results from a retrospective case series (153 children). Patients were not randomized to a treatment group, and there was no control group. All patients were not followed for the same amount of time.
• Each child was used as his/her historical control.
• Children who did not do well with the lenses may have dropped out and this could create bias in the long-term results.

Each practitioner needs to come to their own conclusions about how to interpret research and how it may impact or influence his/her decisions with patients. Further research is needed to understand the clinical importance of the observed differences as well as long-term outcomes.

Implications
The higher amounts of peripheral plus power found in this lens may be contributing to a stimulus which inhibits AL growth and therefore myopia progression. The importance of this data is that it comes from real-world practice with clinicians treating patients that they see every day.

*NaturalVue Multifocal is a commercially available daily disposable, center-distance, soft multifocal contact lens with an aspheric extended depth of focus design.
**Data was less for axial length measurements due to lack of measurement instrumentation available in some practices at the time the study began. Data calculated through 3 years (35 months) in a smaller sample.
